

Example $\Rightarrow$ Q-Learning - Learns the value of actions using an agent.

$\Rightarrow$ SARSA - Updates its value based on current / next steps

$\Rightarrow$ Example how a self driving car learns for good decisions its rewarded and punished for wrong dec.

Martemy Exercise

1. Predicting the price of a house based on square footage and number of rooms (labeled data)

Solution

= House prices are a continuous outcome variable

Hence linear regression is an efficient mechanism of predicting and establishing a relationship between input features such as size, location, age against price

2. Clustering customers into groups based on behaviour

Since it is a natural human experience, using unsupervised learning, K-~~Means~~ Means clustering will help group the data well
